ELECTROSTATIC COATER WITH POWER  
TRANSMISSION FREQUENCY ADJUSTER

FIELD OF THE INVENTION

5           The present invention relates to an electrostatic  
coater (or painting device) and in particular to adjustment  
of frequency of a high-frequency low voltage supplied to an  
electrostatic painting device with a high-voltage booster  
circuit.

10

BACKGROUND OF THE INVENTION

As is also disclosed in Japanese Patent Application  
Public-disclosure No. 10-128170, an internal booster-type  
electrostatic spray gun incorporating a high-voltage  
15 booster circuit has been developed as an electrostatic  
painting device. Such an electrostatic painting device, as  
is schematically described in Fig. 1, consists of a high-  
frequency low-voltage generator 1, an electrostatic spray  
gun (electrostatic painting device body) 2, a low-voltage  
20 cable 3, an air supplier (which is not shown) and a paint  
material supplier (which is not shown). A high-voltage  
booster circuit 201 comprises a transformer 202, a multiple  
voltage rectifier circuit 203, a resistor 204 and an output  
terminal 205. The high-frequency low-voltage generator 1  
25 converts a voltage from a commercial alternating-current  
power supply to a DC voltage of 12V via a rectifier 101 and  
DC-DC converter 102. The thus obtained DC voltage is  
supplied to the intermediate point of the primary side coil

of the transformer 202 via a line 103 and low-voltage cable  
3. The ends of the primary side coil are connected to the  
collectors of transistors 104 and 105 respectively via the  
low-voltage cable 3 and their emitters are grounded by a  
5 common line 106. From an oscillation control circuit 107  
to the bases of the transistors 104 and 105 are provided  
~~driving signals which are in 180-degree phase shift with~~  
each other, whereby the transistors 104 and 105 are turned  
on alternately at frequencies of the driving signals. The  
10 multiple voltage rectifier circuit 203, resistor 204 and  
output terminal 205 are connected to the secondary side  
coil of the transformer 202. The transformer 202 boosts  
the primary side voltage by dozens times, which is further  
boosted by the multiple voltage rectifier circuit 203 (by  
15 ten times in this example) to obtain a DC voltage of - 40kv  
~ - 90kv.

The high-voltage booster circuit incorporated in the  
internal booster-type spray gun has an intrinsic parallel  
resonance frequency (frequency at which a consumed current  
20 becomes minimum: hereafter referred to as an antiresonant  
frequency) attributable to its unique hardware structure,  
and when a voltage of such an antiresonant frequency is  
supplied to a high-voltage booster circuit, power can be  
converted to high voltages most efficiently. In other  
25 words, when a voltage of an antiresonant frequency is  
supplied, a current consumed at a high-voltage booster  
circuit is small, whereby a life of a transformer can be  
maximized while a load to be caused on the spray gun can be

minimized. Further, as it is possible to generate a maximum voltage, efficient utilization of a voltage becomes viable.

Fig. 2 is a graph representing a change in current I consumed by a high-voltage booster circuit of an electrostatic spray gun when frequency  $f$  of an alternating-current low-voltage sent from a high-frequency low-voltage generator to the high-voltage booster circuit is varied and a change in boosted negative DC voltage  $V$ . As can be seen from Fig. 2, the DC voltage  $V$  does not change much in the neighborhood of the antiresonant frequency whereas the current  $I$  changes significantly. In this example, when the device is driven at frequencies at which the consumed current  $I$  exceeds approximately 1A, the transformer is likely to be damaged by heat. Therefore, it is ideal that the device be driven at driving frequency  $f_0$  at which the consumed current  $I$  becomes minimum, that is, about 0.2A.

Dispersion arising during the manufacture of high voltage booster circuits, for example, dispersion in electronic components of circuits sometimes results in disadvantageous fluctuation of an intrinsic antiresonant frequency of a high-voltage booster circuit. Further, when voltage supply from a high-frequency low voltage generator shifts from a high-voltage booster circuit for generating a voltage of, for example, - 40kv to a high-voltage booster circuit for generating a voltage of, for example, - 90kv, an optimum transmission frequency cannot be specified. Still further, when a technical specification of a high-

voltage booster circuit per se is changed, for example, a transformer thereof is improved or modified with a view to cost reduction, etc., an antiresonant frequency specific to the high-voltage booster circuit also changes.

5           If a high frequency low voltage whose frequency does not coincide with an antiresonant frequency specific to a high-voltage booster circuit is supplied to the high voltage booster circuit, an excess current flows into a transformer of the high voltage booster circuit to cause  
10 failure and a rated output is not generated. Therefore, when an intrinsic antiresonant frequency fluctuates beyond the referential scope as a result of dispersion arising during manufacture of a high-voltage booster circuit, an electrostatic spray gun incorporating the high voltage  
15 booster circuit is considered to be defective and thus, productivity substantially declines.

On the other hand, a volume for adjusting a frequency may be attached to the oscillation control circuit 107 of the high frequency low voltage generator 1 indicated in  
20 Fig. 1 to initialize an oscillation frequency at the time of assembly of the high frequency low voltage generator 1. For example, a transmission frequency is set to be about  $f_x$  in the case of a high voltage booster circuit cartridge for - 60kv (natural antiresonant frequency =  $f_x$ ), whereas a  
25 transmission frequency is set to be about  $f_y$  in the case of a high voltage booster circuit cartridge for - 40kv (natural antiresonant frequency =  $f_y$ ). When antiresonant frequencies specific to high voltage booster circuits

disperse, an ammeter is connected to the line 103 of the high frequency low voltage generator 1 and a volume is adjusted by monitoring a current value read by the ammeter to set, as an intrinsic antiresonant frequency, a frequency  
5 at which the current value becomes minimum. However, initialization or resetting of a frequency while monitoring an ammeter can be troublesome.

Given the aforementioned problems of prior art, it is an object of the present invention to provide an  
10 electrostatic painting device with a transmission frequency adjustment device which can automatically adjust a transmission frequency such that a consumed current running in the high voltage booster circuit does not exceed a certain value.

15

#### SUMMARY OF THE INVENTION

An electrostatic painting device provided with a transmission frequency adjustment device of the present invention comprises a high voltage booster circuit provided  
20 inside the body of the electrostatic painting device to rectify a high frequency low voltage and generate a DC high voltage for electrostatic painting, a high frequency low voltage generator provided independently of the body of the electrostatic painting device to generate a high frequency  
25 low voltage, a low voltage cable connecting the high frequency low voltage generator to the high voltage booster circuit, current sensor means for detecting a current value corresponding to a value of an intrinsic consumed current

at the high voltage booster circuit and frequency control means for adjusting a frequency of a high frequency low voltage such that a value of a current detected by the current sensor means does not exceed a certain value.

5           According to an embodiment of the present invention, the frequency control means exercises control for  
-----determining a driving frequency to the high voltage booster  
circuit such that a value of a current detected by the  
current sensor means becomes a minimum value. The current  
10 sensor means is installed in the high frequency low voltage  
generator to detect a current guided to the low voltage  
cable. The frequency control means can operate either when  
a power switch of the electrostatic painting device is  
closed or at the set times. The electrostatic painting  
15 device is further provided with an abnormality indication  
means for indicating abnormality when a value of a current  
detected by the current sensor means exceeds a  
predetermined value. The frequency control means adjusts a  
frequency of a high frequency low voltage when abnormality  
20 is indicated.

#### BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a schematic system diagram of a conventional electrostatic painting device.

25           Fig. 2 is a graph representing a change in a relationship between a frequency and a consumed current and a change in a relationship between a frequency and a generated DC voltage.

Fig. 3 is a schematic system diagram indicating an embodiment of an electrostatic painting device provided with a transmission frequency adjustment device of the present invention.

5        Fig. 4 is a flow chart depicting an embodiment of a transmission frequency adjusting operation of the present invention.

Fig. 5 is a graph representing a mode of an operation for searching an optimum driving frequency depicted in  
10    Fig. 4.

#### PREFERRED EMBODIMENT OF THE PRESENT INVENTION

Fig. 3 is a schematic system diagram indicating an electrostatic painting device provided with a transmission  
15    frequency adjustment device of the present invention. In Figs. 1 and 3, like numerals denote like components. In the high frequency low voltage generator 1 in Fig. 3, the current detection sensor 11 is connected to the line 103 applying a 12V output from the DC-DC converter 102 to the  
20    low voltage cable 3. The current detection sensor 11 may be a search coil, etc., and anything can be used as the current detection sensor 11 in so far as it can detect a value proportional to a value of a current flowing in the line 103. A current flowing in the line 103 is a current  
25    on the primary side of the transformer 202 of the high voltage booster circuit 201 and corresponds to a current consumed by the high voltage booster circuit 201. A value of a current detected by the current detection sensor 111

is converted to a digital signal by an A/D (analog/digital) converter to be output to the frequency control circuit 112. The frequency control circuit 112 stores a frequency adjusting program, in accordance with which a signal of an  
5 input current value is processed. If it transpires that the thus processed signal exceeds a threshold, a warning indication signal is output to warning indication means 113.

In response to an output of the warning indication signal, the warning indication means 113 turns on a warning lamp  
10 and/or sounds alarm. The frequency control circuit 112 adjusts an increase/decrease in an oscillation frequency of the oscillation control circuit 107 in accordance with the frequency adjusting program. Further, the search start button 114 is connected to the frequency control circuit  
15 112, and when the search start button 114 is operated, a predetermined sub-routine of the frequency adjusting program starts to perform an operation for searching an optimum driving frequency.

Fig. 4 is a flow chart depicting a processing  
20 operation performed in accordance with the frequency adjusting program stored in the frequency control circuit 112. At step S1, the frequency control circuit 112 receives a current value  $a_0$  detected by the current detection sensor 111. Next, at step S2, the current value  
25  $a_0$  is compared with a threshold A representing a safe driving boundary of the frequency. If the current value  $a_0$  is less than the threshold A, it is determined that the current oscillation frequency of the oscillation control

circuit 107 is adequate and the processing operation proceeds to step S3, where the high voltage booster circuit 201 is driven at the current oscillation frequency to operate the electrostatic spray gun. On the other hand, if  
 5 it transpires at step S2 that the current value  $a_0$  has exceeded the threshold A, the processing operation proceeds to step S4, where the oscillation control circuit 107  
 outputs a warning signal to the warning indication means 113 to indicate warning. Next, the processing operation  
 10 proceeds to step S5, where an operator finds abnormality of a driving frequency from the warning indication and presses the search start button 114 to output a search start signal to the frequency control circuit 112. The processing operation further proceeds to step S6, where a frequency  
 15 adjusting program receives a search start signal and starts an operation for searching an optimum driving frequency.

The operation for searching an optimum driving frequency is performed at step S6 as follows. As is indicated in Fig. 5, a frequency band within the range of  
 20 search is divided into a plurality of sections (N sections in this example) to obtain a plurality of driving frequencies  $f_i$  ( $i = 1, 2, 3 \dots N$ ;  $f_1 < f_2$ ), and the high voltage booster circuit 201 is driven successively at the thus obtained different driving frequencies to find current  
 25 values  $a_i$  ( $i = 1, 2, 3 \dots N$ ) corresponding to the respective driving frequencies  $f_i$  and store the same. Next, the smallest one of the stored current values  $a_i$  is selected and the driving frequency  $f_i$  corresponding to the thus selected

smallest current value  $a_1$  is determined to be an optimum driving frequency. The processing operation then proceeds to step S7, where the high voltage booster circuit 201 is driven at the thus chosen optimum driving frequency  $f_1$  to  
5 operate the electrostatic spray gun.

The above embodiment employs a manner for obtaining  
----- detected current values corresponding to a plurality of  
driving frequencies to determine an optimum driving frequency. However, the present invention is not limited  
10 to the above manner and other known methods for determining an optimum driving frequency such as a method for estimating an optimum driving frequency from a driving frequency - consumed current characteristic curve, at which a current value becomes the smallest, etc. may be employed.  
15 Further, although in the above embodiment a driving frequency at which a current value becomes the smallest is determined, frequencies corresponding to detected current values not more than a predetermined value, for example, a threshold B ( $B = 0.6 \times$  the aforementioned threshold A) may  
20 be determined to be driving frequencies.

Still further, a processing operation in accordance with the frequency adjusting program may be performed when a power switch of the high-frequency low-voltage generator 1 is closed or at the times pre-set by the oscillation  
25 control circuit 107 or when the high voltage booster circuit 201 is exchanged, modified, etc.

An electrostatic painting device of the present invention is designed such that an optimum frequency at

which a minimum consumed current value specific to a high-voltage booster circuit incorporated in the electrostatic painting device or permissible consumed current value is obtained can be automatically generated at a high-frequency  
5 low-voltage generator. Therefore, frequencies affected by dispersion arising during manufacture of high voltage  
-----booster circuits can be easily adjusted to be an optimum  
frequency to compensate for manufacturing dispersion.  
Further, if a new spray gun provided with a high voltage  
10 booster circuit of a different voltage specification is employed at a job site, the same high frequency low voltage generator as used for the old spray gun can be employed as it is to readily adjust a frequency of the high voltage booster circuit of the new spray gun to an optimum  
15 frequency. Thus, an electrostatic painting device of the present invention is always driven at an optimum frequency, which prolongs a life of the apparatus and improves quality of products manufactured by the apparatus.

In the present invention, an electrostatic spray gun  
20 for atomizing a painting material by compressed air and charging particles of the material is described as an embodiment of an optimum electrostatic painting device. However, the present invention is in no way restricted by the above embodiment and is applicable to, for example, an  
25 electrostatic rotary atomization type painting device for discharging a painting material in the form of a thin film from the rim of a cup rotating at a high speed by means of a centrifugal force of the cup and atomizing the material

in the form of a thin film by means of repulsion of static electricity instead of utilizing compressed air.

The embodiment described above is given as an illustrative example only. It will be readily appreciated  
5 that many deviations may be made from the specific embodiment disclosed in the specification without departing from the invention. Accordingly, the scope of the  
invention is to be determined by the claims.
